## Underlying Thesis of this Presentation

- The semantic web is evolving out of the efforts of three (not entirely distinct) communities.
  - The W3C: RDF and RDF Schema
  - The hypertext community: Topic Maps
  - The AI community: DAML
- To understand the semantic web, we should understand the motivations of these communities.
- To understand DAML, we will look at the subfields of AI that are informing DAML development; the goals of the DAML program; and some tentative DAML architectures.

## A History of Knowledge Representation

- Knowledge representation (KR) is the branch of artificial intelligence (AI) that deals with the construction, description and use of ontologies.
  - How do we model a domain for input into the machine?
- *Ontology* is the branch of philosophy that answers the question "what is there?"
  - Some big names in ontology: Parmenides, Plato, Aristotle, Kant, Pierce, Husserl
- For a program to reason, it must have a conceptual understanding of the world. This understanding is provided by us. Thus we have to answer questions that we've been considering for several thousand years.
- Today, in computer science, an ontology is typically a hierarchical collection of classes, permissible relationships amongst those classes, and inference rules

## State of the Art of AI/KR

- 1970: Semantic Networks
  - Concepts are represented by nodes.
  - Relationships between concepts are represented by arcs.
- 1980: Frame Based Systems
  - Much more meta-data attached to objects.
    - Class, Sub-class hierarchies
    - Attributes, facets, etc.
  - Took us a long way.
    - eg, first expert systems built with kee.
  - Still something missing: a need for rules, variables, quantifiers, etc. is recognized

## State of the Art of AI/KR (contd.)

- 1990: Inference rules added
  - Modern Knowledge base systems.
  - A fairly rich subset of 1<sup>st</sup> order logic
  - recurring research issue: expressiveness vs. efficiency
    - It's easy to add a feature that takes you from one computational complexity level to another. (eg, adding negation kills monotonicity, which means complicated truth maintenance must be implemented.)
    - We will see this again.

## Some Issues in Knowledge Engineering

- How to represent, and reason about temporal objects.
- How to represent, and deal with change.
  - (This has been a problem since the pre-Socratics.)
- Need to be careful with inheritance.
  - Distinction between necessary and *non-necessary* properties.
    - eg, student *isa* person.
    - But a person has the property of always being a person.
    - Obviously, the class *student* does not inherit this property.

## The Agent Computing Paradigm

- The old way of thinking about computer programs: a program
  - » begins executing
  - » takes input
  - » gives output
  - » finishes executing
- The new way: programs
  - » interact with each other
  - » are always active
  - » should be robust (ie, able to deal with the unexpected)

## From Agents to Knowledge Markup

- Almost everything we need to know is on the web.
- What a great resource for agents!
- But ... Agents don't understand web pages.
  - Natural Language processing is too hard for computers, and will remain so for a long time.
- The solution: Knowledge Markup.

## Knowledge Markup in a Nutshell

- A web page describes objects.
  - Datasets, human beings, services, items for sale, etc.
- The semantics of an object are defined by the place it occupies in some domain ontology.
- The basic idea of knowledge markup is to use XML to markup a web page according to the location its objects occupy in the ontology.
- Essentially, knowledge markup is knowledge representation done in XML.

## Generic Knowledge Markup Document

```
<ontology>  
Some URLs  
</ontology>
```

A collection of statements of the form:

```
<Class>  
X  
</Class>  
<Relationship>  
(X,Y)  
</Relationship>
```

## Benefits of KM

- Agents can parse a page, and immediately understand its semantics.
  - No need for natural language processing.
- Searches can be done on concepts. The inheritance mechanisms of the back-end knowledge base obviate the need for keywords.
- Data and knowledge sharing.

## Knowledge Markup Example (Hypothetical)

- You ask the system "Show me all universities near the beach."
- The UCLA page doesn't say anything about the beach, but it does say (through knowledge markup) that it's near the Pacific Ocean.
- UCLA makes use of a geography ontology which includes the rule "Ocean(x) → hasBeaches(x)".
- When your search agent parses the UCLA page, it loads in the relevant ontologies, deduces that UCLA is near the beach, and returns the page.

## Resource Description Framework (RDF)

- RDF was conceived as a way to wrap metadata assertions (eg Dublin Core information) around a web resource.
- The central concept of the RDF data model is the *triple*, represented as a labeled edge between two nodes.
- The subject, the object, and the predicate are all resources, represented by URIs

InfoLoom, Inc.

and Joel Sachs

## RDF Data Model (Contd.)

- We say that <subject> has a property <predicate> valued by <object>.
- A resource may have more than one value for a given property.
- Objects may be valued by literals (instead of resources).
- Triples can be chained together, with the object of one triple being the subject of another.

## RDF Data Model (Contd.)

## RDF Model: Reification

- **Reify:** *To regard or treat (an abstraction) as if it had concrete or material existence.* (Websters)
- Any RDF statement can be the object or value of a statement.
  - ie Graphs can be nested as well as chained.
- This allows us to make assertions about other people's statements.
  - eg "Joel Sachs believes that Michel Biezunski is the partner of Dianne Kennedy"

## RDF Syntax

- An XML syntax has been specified for RDF.
- An RDF document is a collection of assertions in **subject verb object** (SVO) form.
  - There are several accepted abbreviations.

## RDF Schema

- RDF Schema is a frame based language used for defining RDF vocabularies.
  - Introduces properties `rdfs:subPropertyOf` and `rdfs:subClassOf`
  - Defines semantics for inheritance and transitivity.
  - Introduces notions of `rdfs:Domain` and `rdfs:Range`
    - Also provides `rdfs:ConstraintProperty`
- We'll see an example when we look at DAML.

## The Recapitulation of AI Research

- The last 2 years have seen a recapitulation of 40 years of AI history.
  - Data Structures → XML
  - Semantic Networks → RDF
  - Early Frame Based Systems → RDFS

As a mechanism for metadata encapsulation, RDFS works just fine. But it is unsuited for general purpose knowledge representation. This is where the AI community steps in, saying, essentially, "We know how to do this; please let us help."

## The DARPA Agent Markup Language (DAML)

- A five year, \$70 million research effort organised by the US Defense Army Research Project Agency, (the people who brought you the internet).
- Goal: To enable software agents to dynamically identify and understand information sources, and to provide semantic interoperability between agents.
- Activities:
  - Language Specification
  - Knowledge Annotation Tools
  - Construction of DAML aware multi-agent systems
    - The purpose of this last activity is to overcome a "chicken and egg" problem. The semantic web derives its utility from having many sites involved; but no one wants to get involved until a strong utility has been demonstrated.

## DAML (Contd.)

- The DAML research tasks have been distributed amongst 16 US research teams.
  - A veritable "who's who" of the active AI community.
    - Pat Hayes, Debbie McGuinness, Richard Fikes, Drew McDermott, Tim Finin, etc.
  - One of the teams is from the W3C (includes Tim Berners-Lee, Dan Conolly, Ralph Swick, etc.)

## DAML + OIL

- The most recent release of DAML incorporates the European Community's *Ontology Interface Layer* (OIL).
  - a product of the "Joint US/EU Committee on Agent Markup Languages."
- Written in RDFS
- This is a full fledged ontology modeling language.
  - Inference rules are due in the next release.

## The best way to learn DAML is to read DAML

- Here we spend several minutes looking at an example DAML ontology, which will be passed around.

## Issues Facing DAML: Weak RDF semantics

- The semantics of RDF are ill-understood, and much controversial.
  - What does it mean for two classes to be equal?
  - What the heck is an `rdf:container`?
  - Part of the problem is a lack of clarity in the underlying web standards.
    - eg, the notion of URI identity.
- But the semantics of DAML must be clear. (Otherwise, no semantic interoperability.)
- Maybe the RDF-Topic Map Convergence will help clear things up.

## Issues Facing DAML: Legacy Data

- A need to datamine the legacy data, to determine appropriate DAML tags.
  - Work by Helka Folch, R. Holowczak
- Structured data is much easier to deal with than unstructured data: "T2XML"
- Much of our data is stored in databases. We publish it by dynamically generating HTML or XML pages. We could just as easily generate RDF or DAML pages.
  - That is, representing legacy data in DAML might not be as big a problem as it at first seems.

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

## **Issues Facing DAML: Need for Really Good Annotation Tools**

- DAML is not meant to be read or written by human beings.
  - Humans will make assertions through intuitive user interfaces, which will generate the appropriate DAML markup.
- In fact, the markup should “fall out” of the activity of building a web page.
  - This requires some thought.

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## **DAML Example 1: Focused Crawling**

- Special purpose search engines will increasingly replace all-purpose engines.
- The notion of an all-purpose search engine is yielding to that of special-purpose engines.
- Such engines do not want to index irrelevant pages.
- Current “focused crawling” techniques employ heuristics based on text mining, and collaborative filtering.
- A cleaner approach would be for web sites to describe themselves with DAML.
  - An entire site map could be expressed in DAML, along with metadata descriptions of each node in the map.
  - An agent would know precisely which of the site’s pages are worth checking out.

## DAML Example 2: Indexing the Hidden Web

- Search engines – google, infoseek, etc. – work by constantly crawling the web, and building huge indexes, with entries for every word encountered.
- But a lot of web information is not linked to directly. It is "hidden" behind forms.
  - eg [www.allmovies.com](http://www.allmovies.com) allows you to search a vast database of movies and actors. But it does not *link* to those movies and actors. You are required to enter a search term.
- A web-spider, not knowing how to interact with such sites, cannot penetrate any deeper than the page with the form.

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

InfoLoom, Inc.  
Coolheads Consulting  
and Joel Sachs

## Indexing the Hidden Web (Contd.)

- Now imagine that [allmovies.com](http://allmovies.com) had some DAML attached, which said  
"I am [allmovies.com](http://allmovies.com). I am an interface to a vast database of movie and actor information. If you input a movie title into the box, I will return a page with the following information about the movie: ... If you input an actor name, I will return a page with the following information about the actor: ..."

**InfoLoom, Inc.**  
Coolheads Consulting

## Indexing the Hidden Web (Contd.)

- A DAML aware spider can come to such a page and do one of two things:
  - If it is a spider for a specialized search engine, it may ignore the site altogether.
  - If not, it can say to itself: "I know some movie titles. I'll input them (being careful not to overwhelm the site), and index the results (and keep on spidering from the result pages).
- At the least, the search engine can record the fact that  
"www.allmovies.com/execperson?name=x"  
returns information about the actor with name X.

## DAML Example 3: An Environmental Legal Information System

- The goal: interoperate remote sensing and environmental law databases.
- Sample query: Click on an environmental treaty, and ask "What remote sensing data do we have that can help in monitoring compliance of this treaty?"
- The problem: We can't expect the metadata attached to a particular remote sensing dataset to anticipate all queries to which it might be relevant. Reasoning must be done to determine which datasets to return.

## DAML Example 4: Knowledge Sharing/Corporate Memory

- Our problem: NASA is huge, and IT practioners don't know what their colleagues are up to.
  - The wheel often gets reinvented.
- Our plan:
  - Build an ontology which captures the IT work being done at NASA.
  - Mark up projects, toolkits, algorithms, etc. according to this ontology.
  - Harvest the information with DAML aware web-crawlers.
  - Build DAML aware query agents.

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

## DAML Example 4 (Contd.)

- Scientists should be able to tell the query agent the current form of their data (e.g. raw satellite images), their desired output (eg Time Series Forecasts), and get back the series of available tools necessary to perform the transformation.
- We also have a chicken and egg problem here.
  - Research teams don't want to invest time in yet another knowledge technology.
  - So we'll do it for them. We're selecting 20-30 divers projects at Goddard; we will interview the computer scientists, and mark up their efforts.

## DAML Example 5: ittalks.org

- ittalks.org will be a repository of information about information technology (IT) talks given at universities and research organization across America.
- A user's information (research interests, schedule, constraints, etc.) will be stored on their personal DAML page.
- When a new talk is added, the personal agents of interested users will be notified.
- The personal agents will determine, based on schedule, driving time, more refined interest specifications, etc, whether or not to inform the user.

## ittalks.org (Contd.)

- Example Scenario
  - You are going to be in Boston for a few days. You enter this in your schedule, and you are automatically notified of several talks, at several Boston universities, that match your interests. You select one that you would like to attend. You get a call on your cell-phone letting you know when it is time to leave for the talk.

## The Road Ahead

- Enormous synergy between KM, ubiquitous computing, and agents.
  - Start Trek, here we come.
- The concept is clear, but many details need to be worked out.
- Semantic Web systems can be built incrementally.
  - Start small. Even a very modest effort can massively improve search results.

## The Adolescence of XML

**InfoLoom, Inc.**

and Joel Sachs

InfoLoom, Inc.  
Coolheads Consulting

## A common fallacy: DTD is API

- The fallacy is: the structure of an XML resource should also be the API to the information it contains.
  - Trying to make the element structure also be the API makes it impossible to have both a good interchange structure and a good API. The attempt introduces inefficiency and invites unreliability of information interchange.
- The Document Object Model (DOM) is an API to the generic structure of XML resources. It is not and can never be the API to the information sets conveyed by all vocabularies.
  - If, e.g., the XLL vocabulary's functionality gets built into the DOM, what vocabulary's functionality *shouldn't* be built into the DOM?
    - No committee can possibly do all this work!

InfoLoom, Inc.  
Coolheads Consulting  
and Joel Sachs

## Interchange syntax model is a contract

- DTD is a contract between
  - **information creators**
  - **information consumers**
  - applications developers
- DTD enhanced with type checking, lexical typing, etc., is a more detailed contract between the same players

InfoLoom, Inc.  
Coolheads Consulting

## Two sides of one coin

- The interchange syntax model and the abstract API are two aspects of the same information set:
  - Syntax model = consensus about the interchange format of the information set
  - Abstract API = consensus about the abstract properties of the information set

## Flexible Checking: the notion of Information Architecture

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## Architecture Definition Document

- Documentation for an XML architecture:
  - meta-DTD (syntax rules)
  - Natural language documentation of the semantics of each form
- Can be used as a specification by programmers building architectural applications
- Can be used by document creators as a guide to proper usage

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## What Makes an Architecture?

- Point of View: "base" and "client" roles
- "Client" inherits (is derived) from "base"
- Client DTDs inherit from base architectures
- Client meta-DTDs inherit from base architectures (architectures can be derived from other architectures)
- DTDs can be used as base architectures

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## Architectures are about...

- Using constructs with predefined semantics as templates for specific element types
- Reusing software components that are built for defined architectures
- Inheriting semantics from more than one architecture at a time
- Accommodating diverse user groups while maintaining control at a general policy level

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## The Value of Architectures

- Architectures allow user groups to
  - agree on common functionality while not abandoning group-specific semantics
  - use their own terminology
  - integrate architectural elements with group-specific elements (or use multiple architectures) separably, but in a single source document (customized data views)
  - use standardized architectural software

## Names

- What is a name?
  - A property of a named thing?
  - A property of a network?
  - An indicator of semantics?
  - A resource?
  - An address?
  - A label?
  - An identifier?

  - An addressable thing?
  - The content of an addressable thing?
  - The meaning of an addressable thing?

## Concepts: What It's All About

- Need a foundation concept of concept.
- Need a discipline for associating concepts with resources.
- Need to give specific roles to specific kinds of resources.
  - Name resources
  - Address resources
  - Concept-defining resources

## XML "Namespaces"

- XML "Namespaces" are vocabularies. The XML "Namespace" recommendation is a step on the road toward interoperability for XML messages.
- A "namespace" amounts to an abstract "place" where there is a list of element type names (tag names) and/or attribute names.
- URIs specify the namespaces in use.
- There is no requirement that the specified URI is valid, much less that the indicated resource conforms to any sort of specification.
- XML "Namespaces" provide a way for names to be guaranteed to be unique, and *that's all*.

InfoLoom, Inc.  
Coolheads Consulting  
and Joel Sachs

## XML "Namespaces" and expectations

- In some sense, an XML resource that uses the names of an XML "namespace" must inherit from it expectations as to the meaning and conventional use of each of the names.
  - (Right? Otherwise, why use it at all?)

## Do namespaces help with interchange?

```
<hp:hperm  
  xmlns:hp='http://www.gov.ng/hp.x'>  
<hp:thone>UDLINGBLON</hp:thone>  
<hp:kallow>29</hp:kallow>  
<hp:spec>GUINEA FOWL</hp:spec>  
<hp:date>2000 3 9</hp:date>  
</hp:hperm>
```

(Vocabulary in the HP namespace:  
hperm, thone, kallow, spec, date)

I can parse it,  
but what is it?

## XML "Namespaces:" Unresolved issues

- How to express a namespace so it can be shared?  
What is the list of names?
- How to write processing software for a namespace?
- How to determine whether software for a namespace works according to the expectations of other users of the namespace?
- How to determine whether an XML resource conforms to the syntactic and semantic requirements of the namespace?
- How to determine, when information interchange fails, whose software is at fault? (The software that created the XML resource, or the recipient application?)
  - Accountability is vital to interchange.

## XML Vocabularies in open environments

- Ideally, an XML resource is self-describing. Since many XML resources use the same vocabularies, it's efficient to describe them in terms of the vocabularies they use.
- Anybody who receives a well-described XML resource should be able to interpret it accurately.
- Anybody should be able to create an XML resource that uses a vocabulary correctly, so that its recipient will interpret it accurately.
- Vocabularies should be able to support entire industries and areas of human endeavor, in open, multivendor environments.
- Vocabularies should offer huge advantages in efficiency and reliability.

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## XML Vocabularies in closed environments

- Closed syndicates and would-be cartels need to resolve the same issues, so that their XML messages will interoperate.
- It's extremely inefficient for each syndicate to invent the methodologies and tools for guaranteeing reliable vocabulary-based interoperability.
  - It's also a net contraction in the noosphere of the syndicate. Where to find technical expertise? How to maintain it? Etc.
- Enlightened self-interest demands that the same methodologies and tools that support open interoperability be used internally.
- Vocabularies should offer huge advantages in efficiency and reliability.

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

## Methodologies and Tools for Vocabularies

- Vocabularies can be used to make XML resources fully self-describing, fully interchangeable and fully interoperable, down to the last syntactic and semantic feature.
- This can be accomplished using existing W3C and ISO recommendations and standards, all from the XML and SGML families of recommendations and standards.
  - Alternatively, the same principles could be applied using different modeling syntaxes, purpose-built for the Web.
  - ...but if it can be done without reinventing everything, why bother?

- It would be great to be able to document vocabularies more effectively than we can now.

## It's all about addressing

- External metadata (such as topic maps) must be associated with data by means of addresses.
- How can the value of external metadata be protected against losses due to technology change? In other words:
- How can addressing expressions be independent of technology?

## Semantic modeling: emergent properties

- Example of an "emergent" property: The property of being a target of an xlink (considering XLL as a vocabulary).
- All emergent properties of a vocabulary must be described clearly, comprehensively, unambiguously, and formally, because
  - accuracy and reliability are important.
  - the information is expected to be useful in multi-vendor application environments (if not, why inherit a vocabulary at all?).
  - implementation of vocabulary-specific applications must be done at reasonable cost.

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

**InfoLoom, Inc.**  
Coolheads Consulting  
and Joel Sachs

## Semantic validation becomes a side-effect

- Computing an emergent property value often isn't possible without validating the interchanged information on which the computation is based.
  - For example, if an element that inherits from a vocabulary specifies a "start-time" attribute and an "end-time" attribute, we may intend that the duration of time between the start-time and the end-time be calculable and that it fall within a certain range (or at least be non-negative). In any case, we can't calculate the value of the "duration" property unless the start-time and end-time values exist and are amenable to calculation.

## ISO standard property language

- It's called "Property Sets"
- A property set is an XML document that conforms to the ISO standard DTD for property sets.
- Already in commercial use; the software already works with XML.
- Every class of information component ("node"), and every property of every class, has a unique name.
- These names can be used in queries.
- This whole idea is often called "the Grove Paradigm." It's the basis of SGML processing, and the SGML Property Set aided the development of the DOM.

## Designing XML Vocabularies

- Questions to ask:
  - Must certain semantic processing and validation operations be performed by all applications of this vocabulary?
  - Will more than one application have to deal with this vocabulary?
- If so, its syntactic requirements deserve to be made explicit in a DTD (or something like a DTD), and
- A property set (or other explicit Abstract API) defined for it will pay big dividends
  - in software reuse
  - in achieving widespread consensus about what the vocabulary really means
  - in determining what went wrong when vocabulary-mediated information interchange fails

## Groves go beyond XML

- Not all information can be efficiently represented as XML
- Conversion to XML can be expensive
- XML is continuously redefined and evolving
- XML is a property set
- APIs to meanings of schemas, DTDs, and vocabularies are Property Sets

## Groves go beyond the DOM

- The world is more than documents
- DOM is evolving
- DOM is a Property Set
- Properties can be extended or retracted to suit any processing needs, current or future!

## Some definitions of "grove":

- A set of interconnected nodes conforming to ISO/IEC 10744:1997 Annex A.4.
- **Ready-to-run objects.** The application-internal information that is being created, edited, or used by an application.
- The form of information that is **the result of parsing an interchange document** (written in XML, for example).
- Information that is present in an interchange document, but which, for application programming, is structured differently in the grove. **The abstract API to the information set.**

InfoLoom, Inc.  
Coolheads Consulting  
and Joel Sachs

## But that's the DOM, right?

- No. The DOM is an API. A grove is a set of nodes -- no methods.
  - But it's true that an API to a grove of an XML document could serve the same purposes as the DOM.
  - And the DOM is an example of an interface to an XML grove.
- Groves are more powerful, general and sophisticated.

## Use by reference

- Groves allow any component(s) of any resource(s) expressed in any notation(s) (XML or non-XML) to be transcluded into any components of any resources expressed in any notations (XML or non-XML),
- ...without changing any of the resources involved.
- Groves allow there to be a single authoritative copy of each datum, regardless of its notation.
- Groves allow each datum to be expressed in the most cost-effective notation.

## Discovery is a hard problem

- Information is multidimensional, multimedia, multicultural, multilingual, context sensitive and multicontextual.
- The information you're looking for may require that you read and understand it yourself before you can recognize that it is what you need.
- There is an awful lot of information in your own place of business, let alone the Web. The overwhelming majority of it is not what you're looking for.
- Nobody knows what you're looking for but you. (And you yourself may not know.)

## Undiscovery is a hard problem

- How to disqualify irrelevant information?
  - Saying what something is relevant to says nothing about what it's irrelevant to. Neither the absence nor the presence of, e.g., a keyword indicates irrelevance.
  - Need to define a whole universe of possible relevance in order to say what's irrelevant.
- How to disqualify obnoxious information?
  - Pornography vs. art.
  - Medical information (behaviors that risk AIDS, what a healthy breast is supposed to look like) vs. religion/culture
  - Self description is always misleading, usually deleterious to free speech.
  - Value judgments are protected speech, too.

## Dublin Core Metadata Element Set V. 1.1

- Core elements:
  - title
  - subject (keywords)
  - creator
  - description (abstract, etc. of content)
  - publisher
  - contributor
  - date
  - type (genres, categories, etc.)
  - format (physical/digital manifestation)
  - identifier (unique string/number in some formal system)
  - source (derived from)
  - language (some natural language used in content)
  - relation (reference to related resource)
  - coverage (scope of the content)
  - rights (who owns what rights, or how to find out)

## ICE - Information & Content Exchange

- Designed to enable:
  - syndicated publishing networks
  - Web superstores
  - online reseller channels
- XML-based message protocol
  - exchange, update information assets
  - trust relationships (builds on P3P)
  - resellers/aggregators add value; consumers find what they want with less difficulty
- Names to drop:

## ICE, continued

- The ICE protocol defines the roles and responsibilities of syndicators and subscribers,
- defines the format and method of content exchange, and
- provides support for management and control of syndication relationships.
- ICE defines a vocabulary and a messaging protocol.
- Industry-specific vocabularies are expected to be mixed with it.
- "Payload" is an oft-heard word in ICE-land.

## CDF, Channel Definition Format

- Channel Definition Format (CDF) specifies the operation of push channels.
- Like ICE, it defines a mechanism for scheduling delivery of encapsulated content.
- Unlike ICE, CDF has no notion of explicit subscription relationship management, asset management, reliable sequenced package delivery asset repair operations, constraints, etc.

## PICS, Platform for Internet Content Selection

- A way of associating "labels" with internet resources.
- For use by programs running in conjunction with browsers that block access to internet resources.
- Originally for the protection of children's sensibilities, while allowing them otherwise-unimpeded access to the Internet (allowing the Internet to be used with minimal supervision, as a kind of TV-babysitter).
- Numeric values for categories.

## Enabling Global Knowledge Connectivity

- Strings (full text indexes, keyword indexes) are not sufficient for searching information.
- Structures (document types, schemas and taxonomies) are sometimes too constraining to qualify (categorize, describe) information.
- Information should be findable regardless of its format or platform of origin.

**To find information, we need information *finding aids* that go beyond strings, work with all structures, and are platform-independent.**

## How to make findable the information found in:

- Unstructured Sources
  - Create
    - Full text index
    - Subject index (natural language processing)
  - Query the index
- Structured Sources
  - Create
    - Some kind of Database (DOM for XML)
  - Query the Database

## Topics

- Subject is essence of topic.
- Topics have Names.
- Topics have Occurrences.
- Can be associated with other topics.
  - Topics can be instances of other topics.

## Names

- A topic can have 0, 1 or several names.
- Base name and variant names (e.g., Display, Sort)
- Names have scopes
  - Scopes differentiate names by e.g., language, domain, usage, security, etc.
- A scope is a set of topics.

## Occurrences

- Collections of resources that are relevant to a topic.
- Occurrences are grouped by class (e.g., depiction, etc.)
- Occurrences have scope.
- An occurrence can be a subject descriptor.

© 2001, InfoLoom, Inc., Coolheads Consulting and Joel Sachs. All rights reserved.

## Shared subject descriptors

## Subjects

- The subject is the abstract notion which is the invisible heart of every topic.
- The object that describes a subject is called a subject descriptor.
- Subject descriptors can be published, i.e., available for public consumption.

## Subject descriptors: two senses

- A subject descriptor can be used 2 ways:
  - for the subject it describes, and
  - for the subject that is itself.
- You have to say which sense. Default is the subject it describes.

## Merging topic maps

- Two topics that have the same subject descriptor in the same sense become a single resulting topic.
- A topic map can reference the topic maps with which it is supposed to be merged.

## Topic Maps vs. RDFS

- Built from the top down.
  - First we define the topics, with pointers to resources.
  - Then we can make those pointers bidirectional to enable cross-referencing.
- Motivated by problems of electronic publishing.
- Everything is a topic.
- Intuitive
- Built from the bottom up.
  - We annotate a document with RDF.
  - Then we parse all the RDF pages and build an index.
- Motivated by problems of library science and knowledge sharing.
- Everything is a resource.
- Hard to understand
